Experiment -5

Q) You are given 'n' strings stored in memory. Then m queries follow. For each query string s, determine whether there exists a stored string t such that t and s differ in exactly 1 position.
For every query, print "Yes" or "No"

Code)
```
# include <bits/std c++.h>
using namespace std;

int main() {
    int n, m;
    cin >> n >> m;
    vector <string> words (n);
    for( int i=0; i<n; i++){
        cin >> words [i];
    }
    while (m--) {
        string q;
        cin >> q;
        bool found = false;
        for (string s: words ){
            if (s.size() != q.size()) continue;
            int diff = 0;
            for (int i = 0; i < s.size(); i++){
                if (s[i] != q[i]) diff++;
                if (diff > 1) break;
            }
            if (diff == 1){
                found = true;
                break;
            }
        }
}
```

```
        if (found) cout << "Yes\n";
        else cout << "No\n";
    }
    return 0;
}
```
